1. We know there are multiple plasticity mechanisms active all at once. Hebbian plasticity underlies learning, but de-stabilises networks. Homeostatic plasticity ensures that even when learning occurs, the network remains in a stable state
2. Generally, though, when we speak of these, we refer to synaptic plasticity only. But, lots of evidence now confirms that, in fact, structural plasticity is active in the adult brain. So not only are synaptic weights changing, the connectivity of networks is changing too!
3. So, it isn't hard to imaging how if changes in synaptic strengths makes plasticity-stability an issue, how the removal and formation of whole synapses would have a much larger effect to plasticity-stability.
4. For the purpose of our analysis, we do not consider the

1. In the adult brain, now that we have the tech to look in at the microscopic structures that form synapses, we see that these are highly dynamic. They sprout and retract, forming and removing synapses. However, this must happen in a way that the brain remains functional: so, are their Hebbian and Homeostatic components of structural plasticity too?

1. The simplest way of studying homeostatic mechanism is to nudge the network out of its stable state. Lesion studies have, for a long time, observed structural changes after peripheral lesioning. A peripheral lesion is where you don't destroy the network itself, but you disrupt the input to it—we'll come to this in detail later.

1. With more tech, neuroscientists have been able to mark, track, and analyse micro-structures that are involved in synapses: boutons, spines, dendritic trees. So, there's recently quite a bit of data from these.

Experimental protocol I

Experimental protocol I

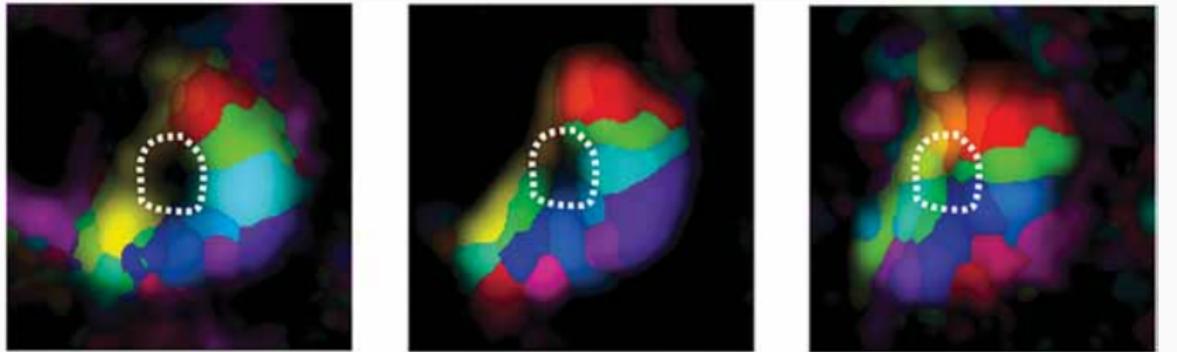

A small brown rat is standing on a white surface next to a color calibration chart. The chart consists of a grid of colored squares, including red, magenta, purple, blue, cyan, green, yellow, and black. A small black horizontal scale bar is located below the chart.

Keck, T. et al. Massive restructuring of neuronal circuits during functional reorganization of adult visual cortex. *Nature neuroscience* **11**, 1162–1167 (2008)

A 3D reconstruction of a rat's visual cortex, showing functional maps. The cortex is represented as a curved surface with different colors corresponding to specific visual fields or receptive fields. A small black horizontal scale bar is located at the bottom left.

1. The protocol is pretty standard. Here, for a study in the visual cortex, the retinal field of a rat or a mouse is mapped.

Experimental protocol II: after peripheral lesion

1. Then, a part of the retina is lesioned. This cuts off inputs to a part of the visual cortex, as shown in the first figure. This forms the Lesion Projection Zone (LPZ). By repeated imaging of the region over months, the reorganisation of the network is tracked.
2. Other lesion studies use similar methods: digit removal, whisker trimming, and so on—anything that cuts off projecting activity on to a set of neurons.

1. In the paper, we simply cite this bit and discuss it briefly, but here I'll explain it in more detail here.
2. Computational modelling stems from evidence from decades years ago. It was established that outgrowth depends on the change in the Calcium concentration in neurons.
3. So, in this figure, we see that a neurotransmitter causes a change in the Calcium of the neuron, and that causes some change in its outgrowth.
4. What this suggests, is that there's an optimal level of Calcium for neurons to have "normal" growth.
5. Based on this, Butz and van Ooyen came up with a framework for modelling structural plasticity. In this, they modelled the rate of change of synaptic elements as a Gaussian function of the neuron's Calcium concentration.

Computational modelling: MSP: turnover

- Synaptic structures (z): excitatory **and** inhibitory post-synaptic, excitatory **or** inhibitory pre-synaptic elements.
- New synapses form when **free** plugs are available: ($z > z_{\text{conn}}$)
- Synapses are deleted if: ($z < z_{\text{conn}}$)
